Announcements

- •Project 1:
 - Deadline: Oct 13th, 2020
- •Homework 2:
- Assignment Project Exam Help
- Deadline: Oct 24th, 20020s://powcoder.com
- Will be posted today Add WeChat powcoder

Thanh H. Nguyen 10/13/20

Reminder: CSPs

- CSPs:
 - Variables
 - Domains
 - Constraints

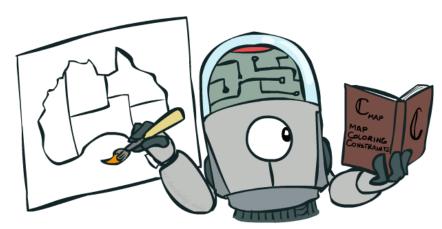

Implicit (provide code to compute)
Explicit (provide a list of the transled to the transled tuples)

Unary / Binary / N-ary

Add WeChat powcoder

Assignment Project Exam Help

- Goals:
 - Here: find any solution
 - Also: find all, find best, etc.

Backtracking Search

```
function Backtracking-Search(csp) returns solution/failure
   return Recursive-Backtracking({ }, csp)
function Recursive-Backtracking (assignment, csp) returns soln/failure if assignment is sometiment return assignment.
   var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp)
   for each value in Cattost opowcodes (200 mignment, csp) do
        if value is consistent with assignment given Constraints [csp] then
            add {var = Adde} Weighnathpowcoder
            result \leftarrow Recursive-Backtracking(assignment, csp)
            if result \neq failure then return result
            remove \{var = value\} from assignment
   return failure
```

Improving Backtracking

General-purpose ideas give huge gains in speed

• Filtering: Can we detect mevitable failure early?

Arc consistency

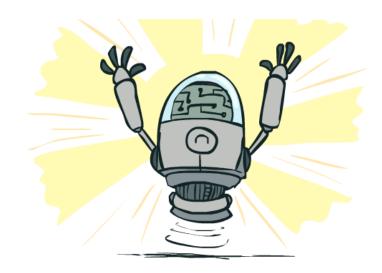

Forward checking

Constraint propagation

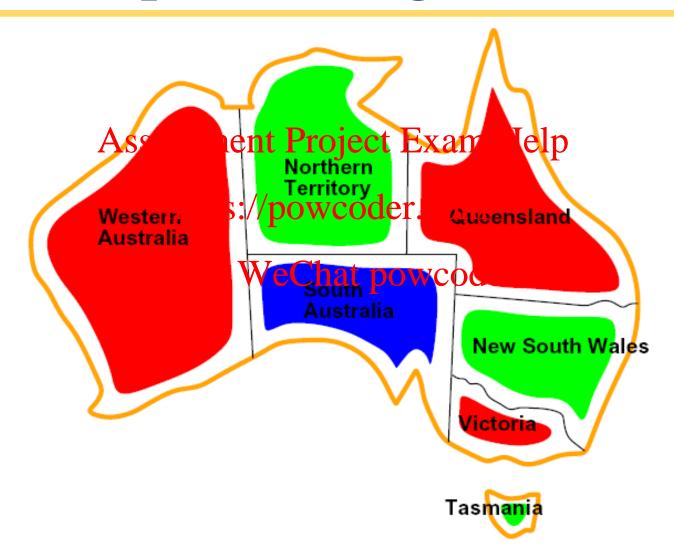

https://powcoder.com

Add WeChat powcoder

- Ordering:
 - Which variable should be assigned next?
 - In what order should its values be tried?
- Structure: Can we exploit the problem structure?

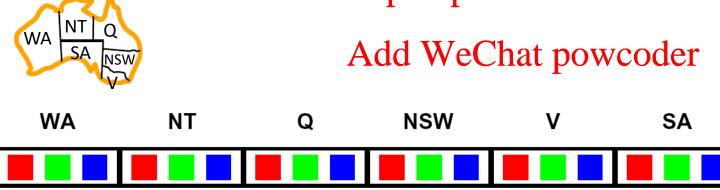

Example: Map Coloring

Example: Map Coloring

- An arc $X \to Y$ is consistent iff for *every* x in the tail there is *some* y in the head which could be assigned without violating a constraint
- Enforcing consistency of X_{SS} Signifilter Project of that it is make $X \to Y$ consistent
- Forward checking: Enforcing consistency of arcs pointing to each new assignment https://powcoder.com

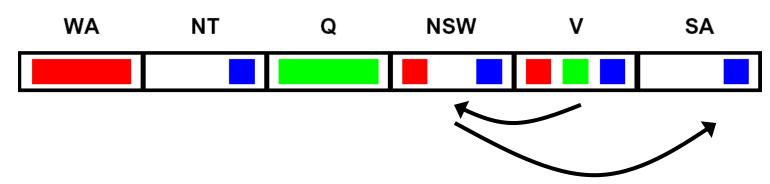

Example: Map Coloring

- Constraint propagation: enforce arc consistency of entire CSP
 - Maintain a queue of arcs to enforce consistency
- Important: If X losessismunat, Reighbersof Repeat to be rechecked!
 - After enforcing consistency on $X \to Y$, if X loses a value, all arcs pointing to X need to be added back to the queue

Add WeChat powcoder

Ordering

Ordering: Minimum Remaining Values

- Variable Ordering: Minimum remaining values (MRV):
 - Choose the variable with the fewest legal left values in its domain

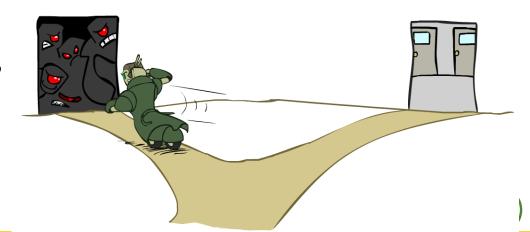

Assignment Project Exam Help

https://powcoder.com

Add WeChat powcoder

- Why min rather than max?
- Also called "most constrained variable"
- "Fail-fast" ordering

Ordering: Least Constraining Value

- Value Ordering: Least Constraining Value
 - Given a choice of variable, choose the *least* constraining value
 - I.e., the one that rules Assignment Projects Fix am the remaining variables
 - Note that it may take some typespulpation der.com determine this! (E.g., rerunning filtering)

Add WeChat powcoder

- Why least rather than most?
- Combining these ordering ideas makes 1000 queens feasible

Structure

Problem Structure

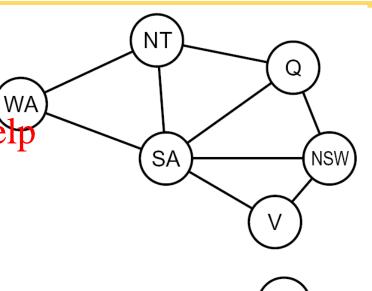

- Extreme case: independent subproblems
 - Example: Tasmania and mainland do not interact

Assignment Project Exam Help

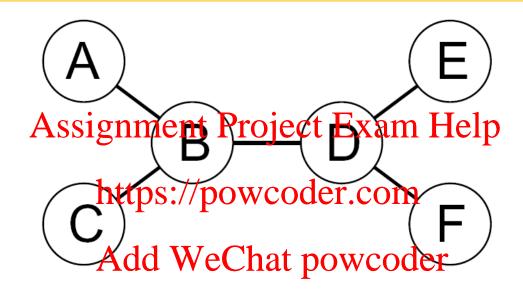

• Independent subproblems are identifiable as connected components of constraint graph

Add WeChat powcoder

- Suppose a graph of n variables can be broken into subproblems of only c variables:
 - Worst-case solution cost is $O((n/c)(d^c))$, linear in n
 - E.g., n = 80, d = 2, c = 20
 - $2^{80} = 4$ billion years at 10 million nodes/sec
 - $(4)(2^{20}) = 0.4$ seconds at 10 million nodes/sec

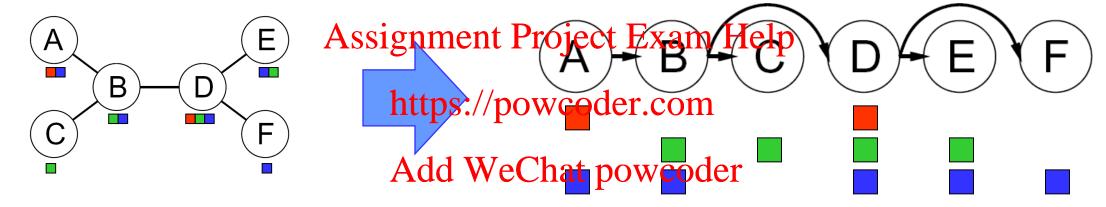

Tree-Structured CSPs

- Theorem: if the constraint graph has no loops, the CSP can be solved in O(n d²) time
 - Compare to general CSPs, where worst-case time is O(dn)

Tree-Structured CSPs

- Algorithm for tree-structured CSPs:
 - Order: Choose a root variable, order variables so that parents precede children

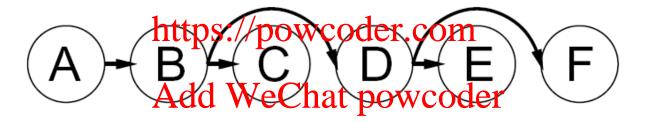

- Remove backward: For i = n : 2, apply RemoveInconsistent(Parent(X_i), X_i)
- Assign forward: For i = 1 : n, assign X_i consistently with Parent(X_i)
- Runtime: O(n d²) (why?)

Tree-Structured CSPs

- Claim 1: After backward pass, all root-to-leaf arcs are consistent
- Proof: Each X→Y was made consistent at one point and Y's domain could not have been reduced thereafter (because Y's children were processed before Y)

Assignment Project Exam Help

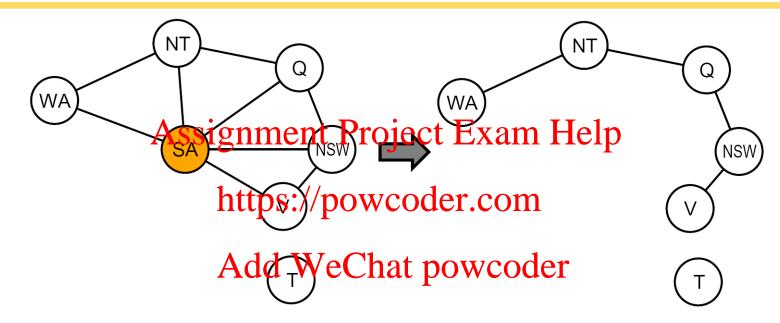

- Claim 2: If root-to-leaf arcs are consistent, forward assignment will not backtrack
- Proof: Induction on position
- Why doesn't this algorithm work with cycles in the constraint graph?
- Note: we'll see this basic idea again with Bayes' nets

Improving Structure

Nearly Tree-Structured CSPs

- Conditioning: instantiate a variable, prune its neighbors' domains
- Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size c gives runtime O((dc) (n-c) d2), very fast for small c

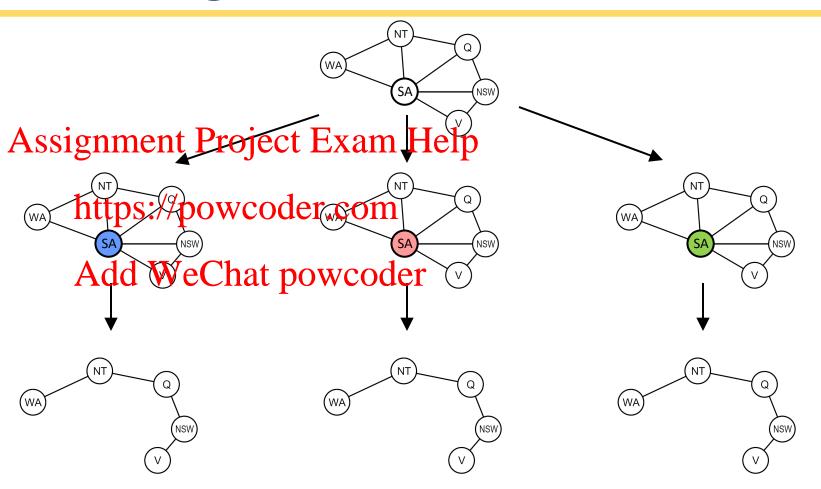

Cutset Conditioning

Choose a cutset

Instantiate the cutset (all possible ways)

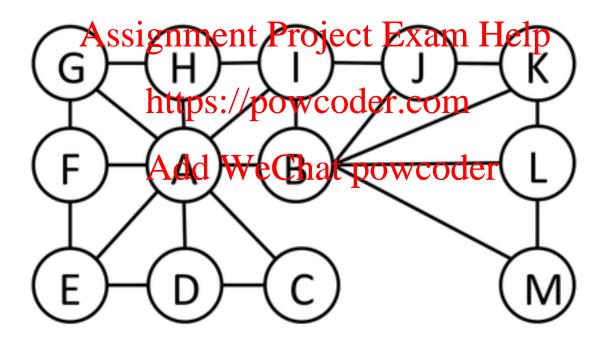

Compute residual CSP for each assignment

Solve the residual CSPs (tree structured)

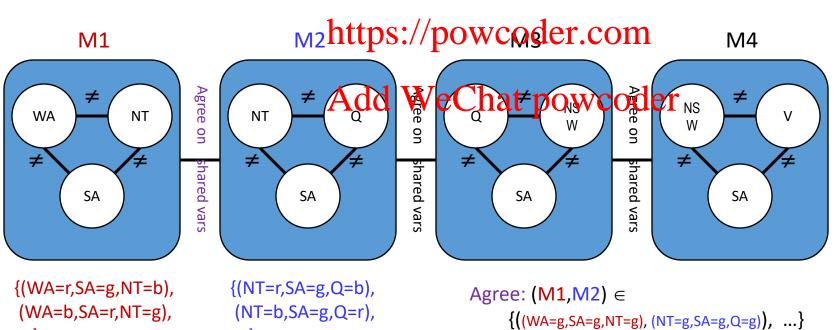

Cutset Quiz

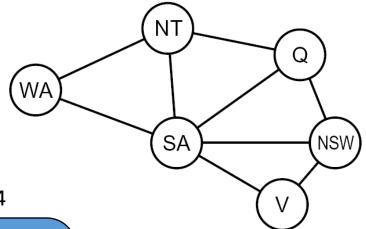

•Find the smallest cutset for the graph below.

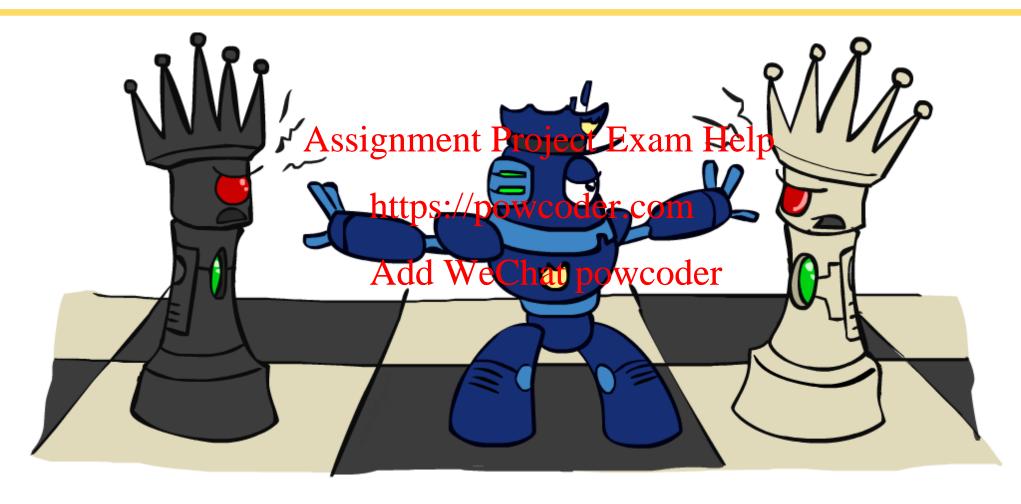

Tree Decomposition*

- Idea: create a tree-structured graph of mega-variables
- Each mega-variable encodes part of the original CSP
- Subproblems overlap to ensure consistent solutions Assignment Project Exam Help

Iterative Improvement

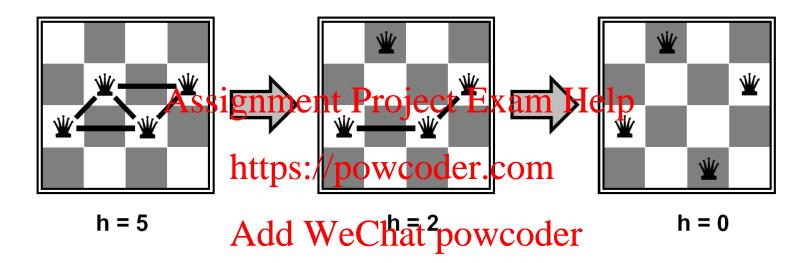

Iterative Algorithms for CSPs

- Local search methods typically work with "complete" states, i.e., all variables assigned
- To apply to CSPs: Assignment Project Exam Help≠
 - Take an assignment with unsatisfied constraints
 - Operators reassign variable https://powcoder.com
 - No fringe! Live on the edge. Add WeChat powcoder
- Algorithm: While not solved,
 - Variable selection: randomly select any conflicted variable
 - Value selection: min-conflicts heuristic:
 - Choose a value that violates the fewest constraints
 - I.e., hill climb with h(n) = total number of violated constraints

Example: 4-Queens

- States: 4 queens in 4 columns ($4^4 = 256$ states)
- Operators: move queen in column
- Goal test: no attacks
- Evaluation: c(n) = number of attacks

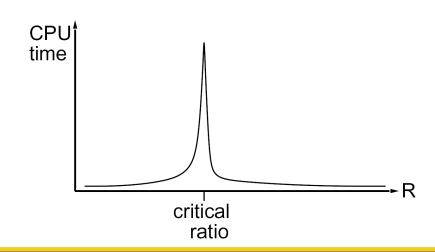

Performance of Min-Conflicts

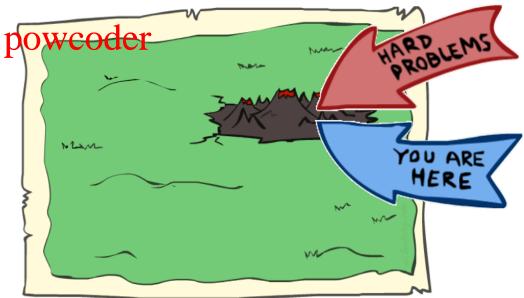

• Given random initial state, can solve n-queens in almost constant time for arbitrary n with high probability (e.g., n = 10,000,000)!

Assignment Project Exam Help

• The same appears to be true for any randomly-generated CSP *except* in a narrow range of the ratio https://powcoder.com

$$R = \frac{\text{number of constraints}}{\text{number of variables}} \text{dd WeChat powcoder}$$

Summary: CSPs

- CSPs are a special kind of search problem:
 - States are partial assignments

Goal test defined by constraints
Assignment Project Exam Help

Basic solution: backtracking search https://powcoder.com

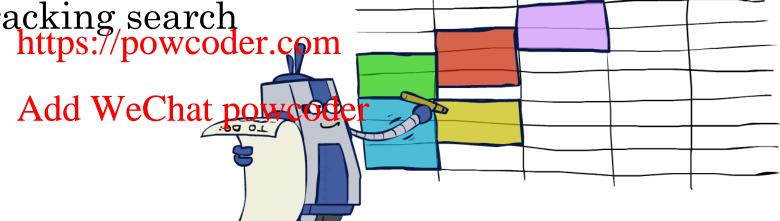

Speed-ups:

Ordering

Filtering

Structure

 Iterative min-conflicts is often effective in practice

Th

Local Search

Local Search

- Tree search keeps unexplored alternatives on the fringe (ensures completeness)
- Local search: improve a single option phtil you can't make it better (no fringe!)

• Generally much faster and more memory efficient (but incomplete and suboptimal)

Hill Climbing

Simple, general idea:

Start wherever

• Repeat: move to the best neighboring state am Help

If no neighbors better than current, quit

• What's bad about this approacher

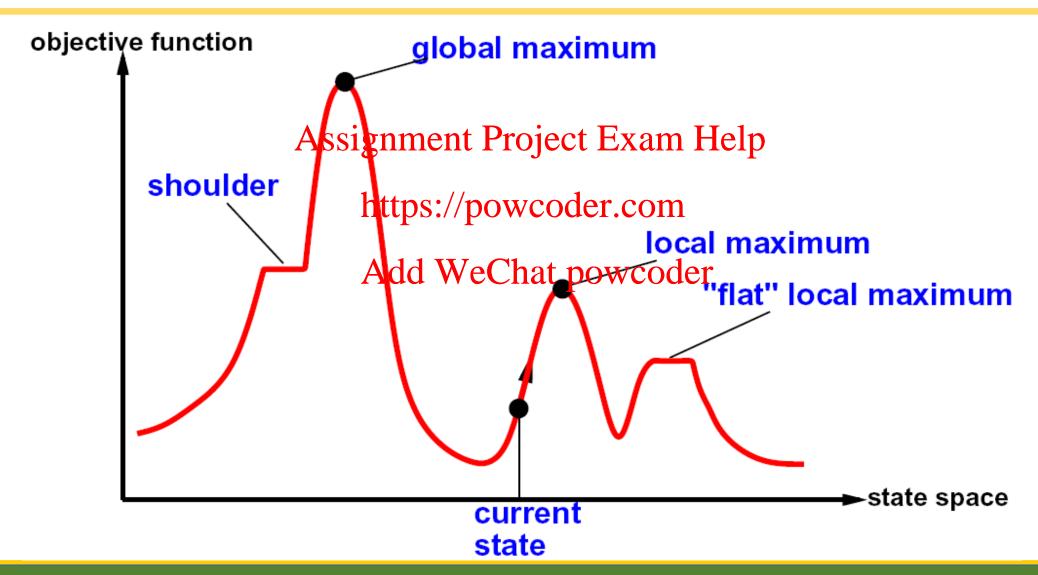

Complete?

Optimal?

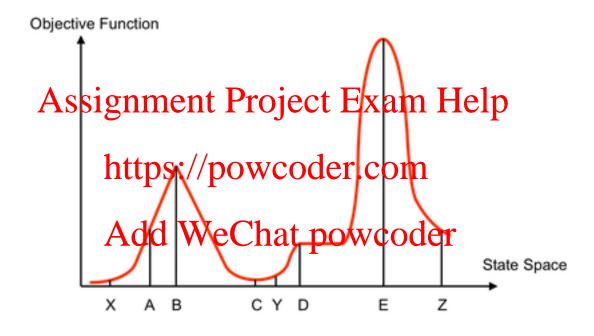

• What's good about it?

Hill Climbing Diagram

Hill Climbing Quiz

Starting from X, where do you end up?

Starting from Y, where do you end up?

Starting from Z, where do you end up?

Simulated Annealing

- Idea: Escape local maxima by allowing downhill moves
 - But make them rarer as time goes on

```
function SIMULATED-ANNEALANG inchement Publication Estate
   inputs: problem, a problem
   schedule, a mapping from time to "temperature" https://powcoder.com
                       next, a node
                        T, a "temperature dd We Chat powcoder steps
   current \leftarrow \text{Make-Node}(\text{Initial-State}[problem])
   for t \leftarrow 1 to \infty do
        T \leftarrow schedule[t]
        if T = 0 then return current
        next \leftarrow a randomly selected successor of current
        \Delta E \leftarrow \text{Value}[next] - \text{Value}[current]
        if \Delta E > 0 then current \leftarrow next
        else current \leftarrow next only with probability e^{\Delta E/T}
```
